ABSTRACT

Generalized generation gap algorithm with parent centric crossover is compared with the Rosenbrock's algorithm. Both algorithms were already presented at the BBOB 2009 workshop where they often showed similar performance. This paper compares them in more detail and adds to understanding of their key features and differences.

Algorithms

Keywords

Benchmarking, Black-box optimization

1. INTRODUCTION

The generalized generation gap (G3) model was introduced by Deb in [1] and was used with the parent centric crossover operator (PCX) introduced in [2]. The performance of the G3PCX algorithm on the BBOB 2009 noiseless test suite was reported in [6]. The Rosenbrock's algorithm was introduced [9]. Its performance on the BBOB 2009 noiseless test suite was reported in [7].

2. ALGORITHM PRESENTATION

The descriptions of the algorithms along with the parameter settings can be found in [6] and [7], respectively. For both algorithms, the crafting effort $\text{CrE} = 0$.

3. RESULTS

Results from experiments according to [4] on the benchmark functions given in [3, 5] are presented in Figures 1, 2 and 3 and in Table 1. The **expected running time (ERT)**, used in the figures and table, depends on a given target function value, $f_t = f_{\text{opt}} + \Delta f$, and is computed over all relevant trials as the number of function evaluations executed during each trial while the best function value did not reach f_t , summed over all trials and divided by the number of trials that actually reached f_t [4, 8]. **Statistical significance** is tested with the rank-sum test for a given target Δf_t (10^{-8} in Figure 1) using, for each trial, either the number of needed function evaluations to reach Δf_t (inverted and multiplied by -1), or, if the target was not reached, the best Δf -value achieved, measured only up to the smallest number of overall function evaluations for any unsuccessful trial under consideration.

Although the algorithms use different principles, both can be described as local search methods. Their performance is very similar. Rosenbrock's algorithm outperforms G3PCX on functions 1, 2, 5, while G3PCX beats Rosenbrock on functions 7, 16, 17, 18, i.e. in this small competition the G3PCX wins 4:3. The results on the other functions are mixed, or neither algorithm solved the problem successfully. Generally, we can say that for dimensions 2 and 3, Rosenbrock's algorithm is faster, while in higher dimensions Rosenbrock's algorithm often does not find good enough solution and G3PCX wins.

In Fig. 1, we can often see a downward peak at the beginning of the ERT ratio lines (functions 1, 3, 4, etc.). The peak means that the model used by Rosenbrock's algorithm must first be adapted to the local neighborhood of the fitness landscape. G3PCX algorithm does not use any global model and thus is able to improve the best/so/far solution almost instantly. After Rosenbrock's algorithm learns its model, it is often faster than G3PCX.

On functions 7 (Step-ellipsoid) and on both Schaffer's functions 17 and 18 neither algorithm works well, but despite that the results of G3PCX are better. The reason for this seems to be the population used by G3PCX.

Looking at Fig. 3, it can be stated that Rosenbrock's algorithm beats G3PCX mainly on the separable functions (where G3PCX exhibits more successful trials, but Rosenbrock's algorithm is faster). G3PCX wins on moderate functions and ill-conditioned functions, where the Rosenbrock's algorithm is inefficient for higher dimensions. On weak-

Figure 1: ERT ratio of G3PCX divided by Rosenbrock versus $\log_{10}(\Delta f)$ for f_1 – f_{24} in 2, 3, 5, 10, 20, 40-D. Ratios $< 10^0$ indicate an advantage of G3PCX, smaller values are always better. The line gets dashed when for any algorithm the ERT exceeds thrice the median of the trial-wise overall number of f -evaluations for the same algorithm on this function. Symbols indicate the best achieved Δf -value of one algorithm (ERT gets undefined to the right). The dashed line continues as the fraction of successful trials of the other algorithm, where 0 means 0% and the y-axis limits mean 100%, values below zero for G3PCX. The line ends when no algorithm reaches Δf anymore. The number of successful trials is given, only if it was in $\{1 \dots 9\}$ for G3PCX (1st number) and non-zero for Rosenbrock (2nd number). Results are significant with $p = 0.05$ for one star and $p = 10^{-\#\star}$ otherwise, with Bonferroni correction within each figure.

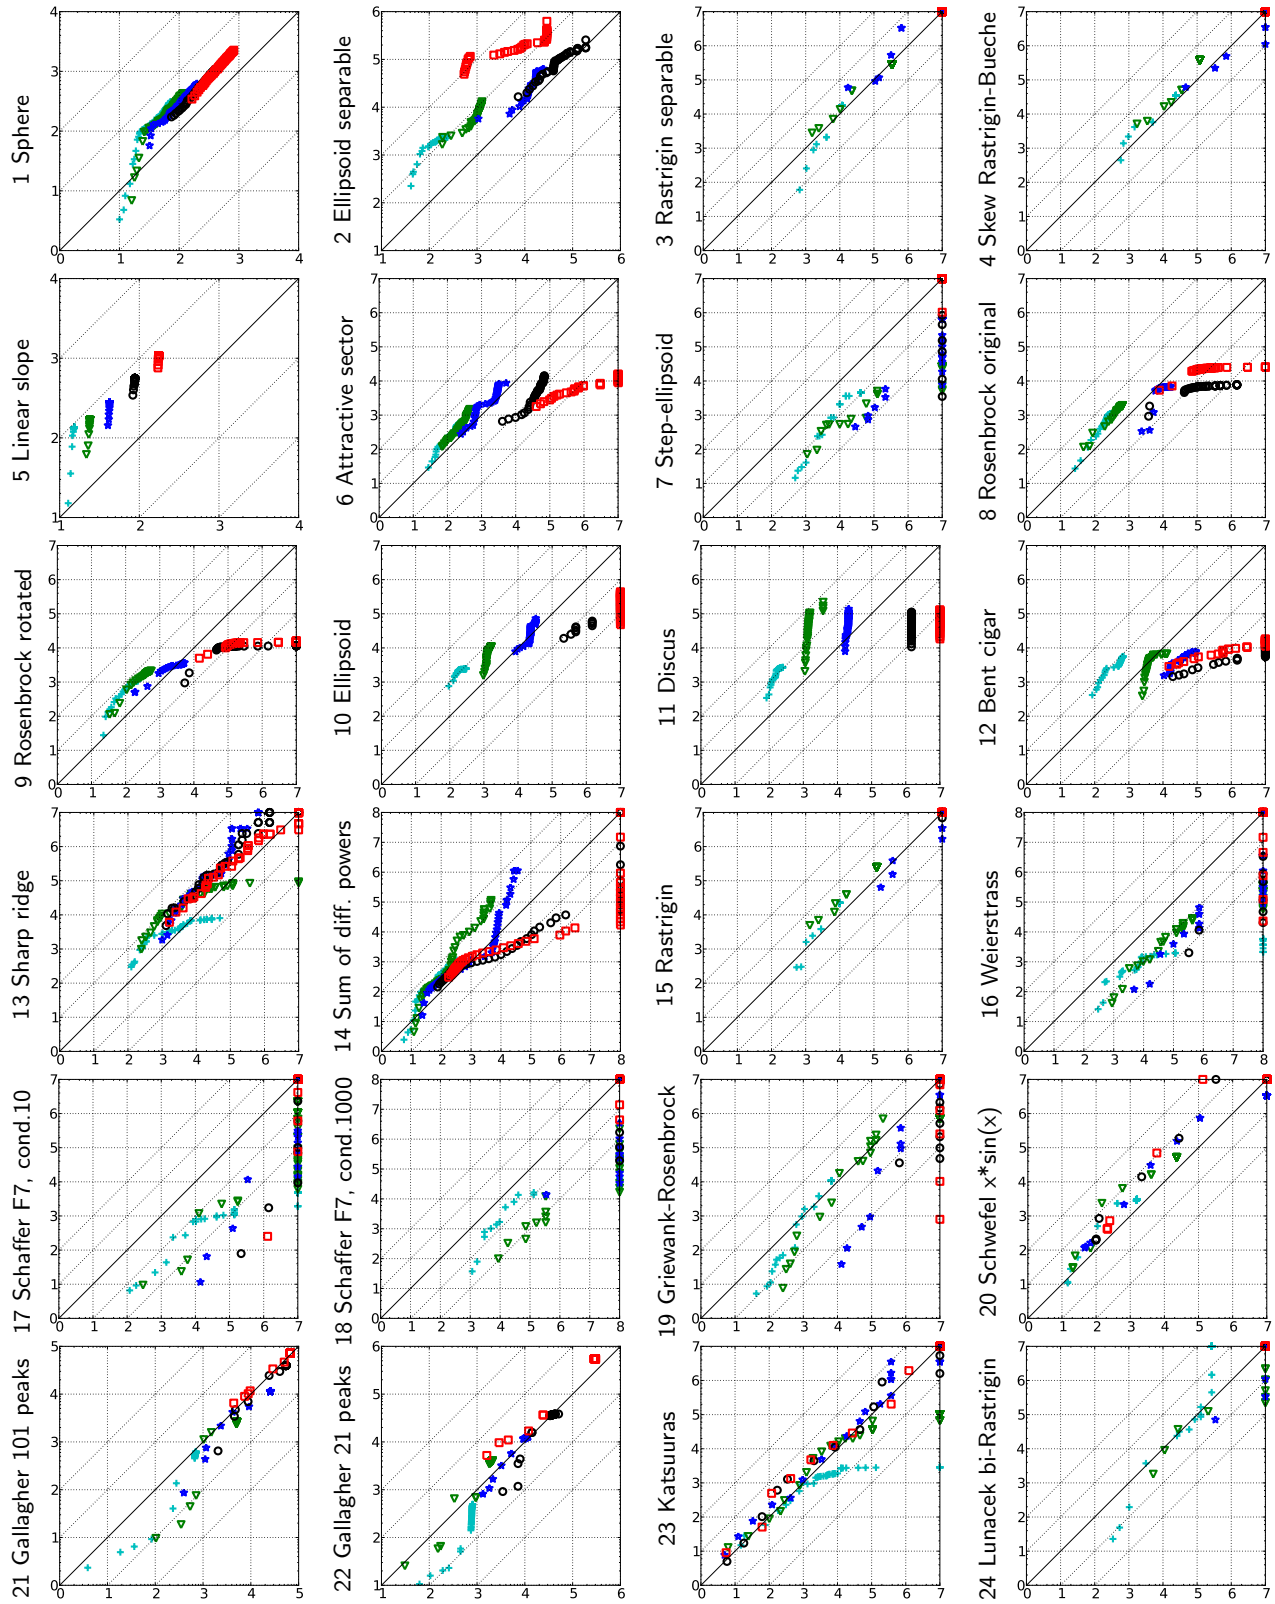

Figure 2: Expected running time (ERT in log10 of number of function evaluations) of G3PCX versus Rosenbrock for 46 target values $\Delta f \in [10^{-8}, 10]$ in each dimension for functions f_1 – f_{24} . Markers on the upper or right egde indicate that the target value was never reached by G3PCX or Rosenbrock respectively. Markers represent dimension: 2:+, 3:△, 5:☆, 10:○, 20:□, 40:◇.

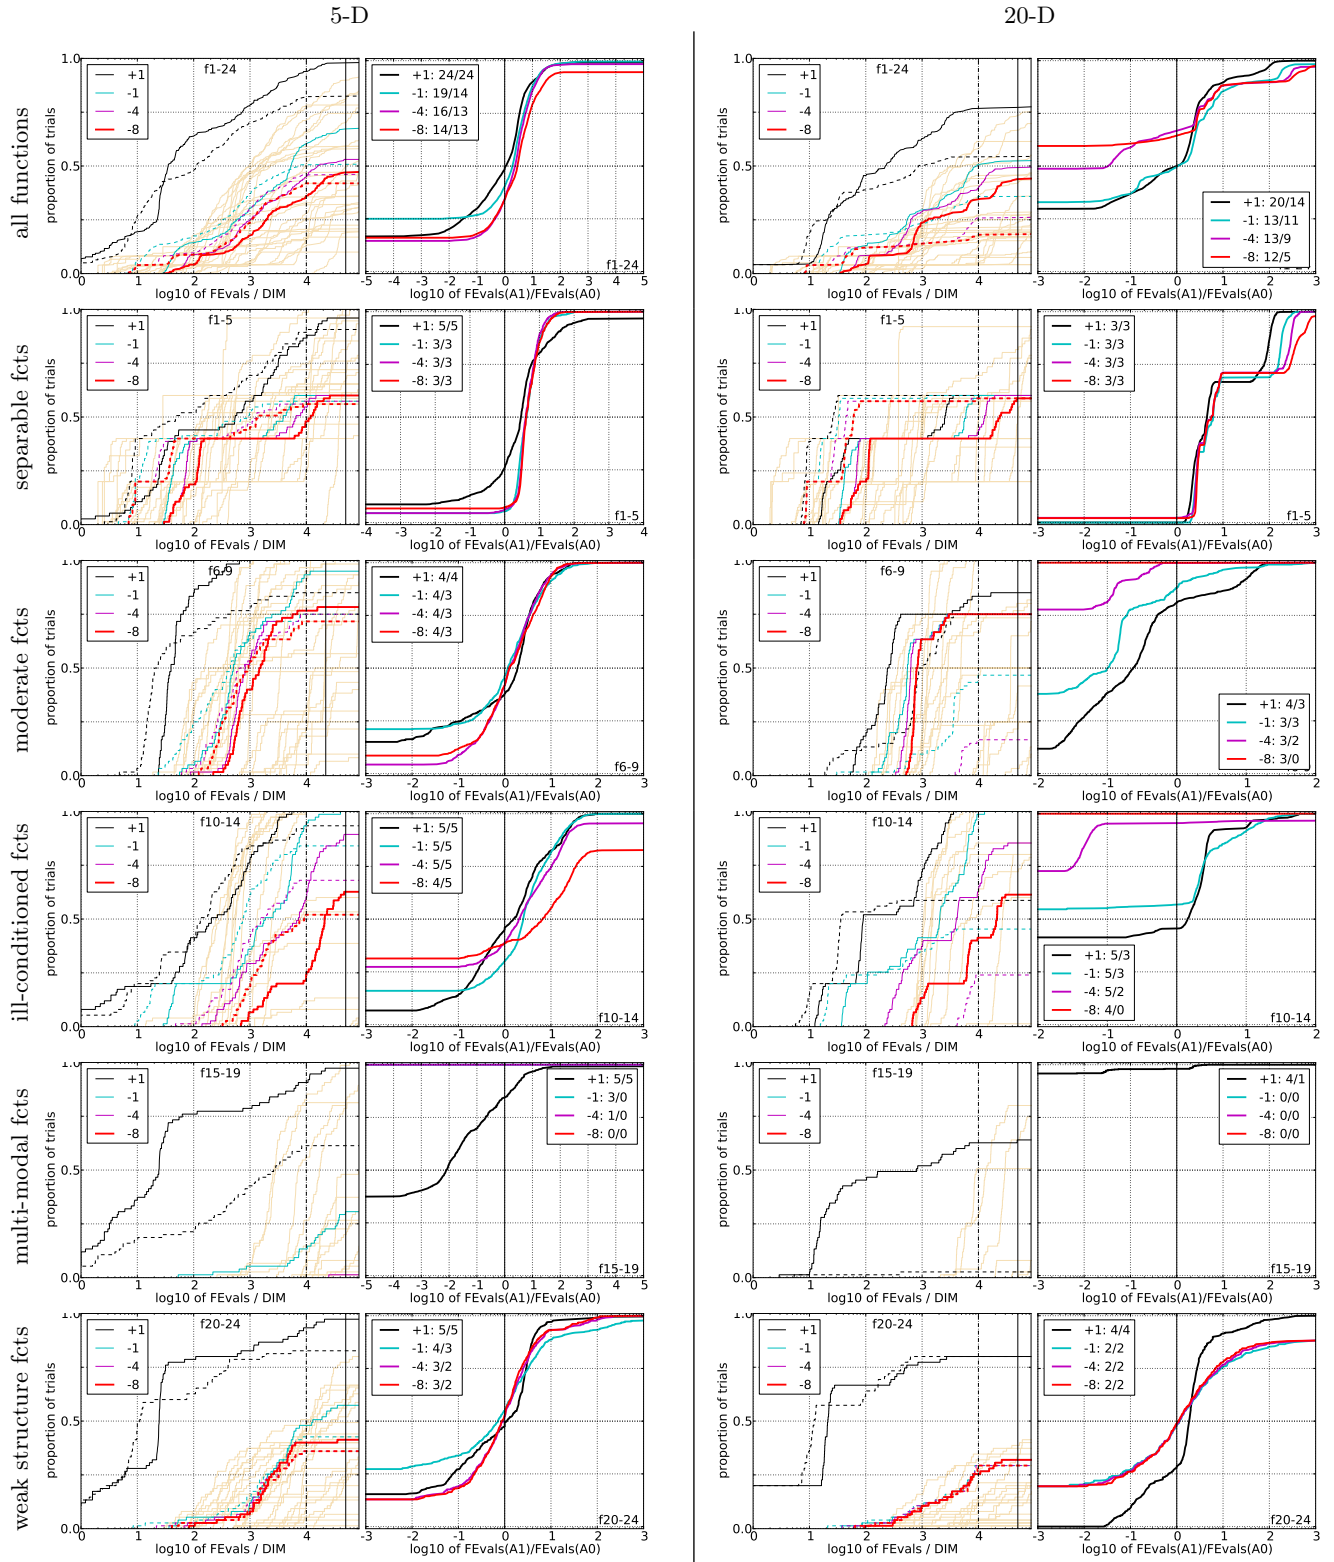

Figure 3: Empirical cumulative distributions (ECDF) of run lengths and speed-up ratios in 5-D (left) and 20-D (right). Left sub-columns: ECDF of the number of function evaluations divided by dimension D (FEvals/D) to reach a target value $f_{\text{opt}} + \Delta f$ with $\Delta f = 10^k$, where $k \in \{1, -1, -4, -8\}$ is given by the first value in the legend, for G3PCX (solid) and Rosenbrock (dashed). Light beige lines show the ECDF of FEvals for target value $\Delta f = 10^{-8}$ of algorithms benchmarked during BBOB-2009. Right sub-columns: ECDF of FEval ratios of G3PCX divided by Rosenbrock, all trial pairs for each function. Pairs where both trials failed are disregarded, pairs where one trial failed are visible in the limits being > 0 or < 1 . The legends indicate the number of functions that were solved in at least one trial (G3PCX first).

Table 2: The average time demands per function evaluation (in microseconds) of the two compared algorithms.

| Dim | 2 | 3 | 5 | 10 | 20 | 40 |
|------------|-----|-----|-----|-----|-----|-----|
| G3PCX | 410 | 420 | 440 | 470 | 540 | 750 |
| Rosenbrock | 310 | 312 | 320 | 334 | 350 | 370 |

structure functions both algorithms did comparably well, while both algorithms failed for multi-modal functions.

4. CPU TIMING EXPERIMENTS

The time requirements of both algorithms are taken from the respective articles, [6] and [7]. The multistart algorithm was run with the maximal number of evaluations set to 10^5 , the basic algorithm was restarted for at least 30 seconds. The experiment was conducted on Intel Core 2 CPU, T5600, 1.83 GHz, 1 GB RAM with Windows XP SP3 in MATLAB R2007b. The comparison of the average time demands per function evaluation are shown in Table 2.
