ABSTRACT

This paper benchmarks the particle swarm optimizer with adaptive bounds algorithm (PSO_Bounds) on the noisefree BBOB 2009 testbed. The algorithm is further augmented with a simple re-initialization mechanism that is invoked if the bounds tend to overlap.

1. INTRODUCTION

Particle Swarm Optimization (PSO) [2, 7] is an optimization method widely used to solve continuous nonlinear functions. It is a stochastic optimization technique that emerged from simulations of the birds flocking and fish schooling behaviors.

The algorithm used in this work incorporates the principles of population-based incremental learning (PBIL) [1] into PSO.

2. ALGORITHM PRESENTATION

A population-based incremental learning (PBIL) approach for continuous search spaces was proposed in [8]. The algorithm explored the search space by dividing the domain of each gene into two equal intervals referred to as the *low* and *high* intervals. A probability h_d , which is initially set to 0.5,

is the probability of dimension number d being in the *high* interval as shown:

$$x_d \in [a, b], h_d = \text{Probability}(x_d > \frac{a+b}{2}) \quad (1)$$

After each generation, this distribution was updated according to the dimension values of the best individual using the following formula:

$$p_d = \begin{cases} 0 & \text{if } x_d^{best} < \frac{a+b}{2} \\ 1 & \text{otherwise} \end{cases} \quad (2)$$
$$h_d^{t+1} = (1 - \alpha) * h_d^t + \alpha * p_d$$

where α is the *relaxation factor* and t is the iteration number. If h_d gets below h_{dmin} or above h_{dmax} , the population gets re-sampled in the corresponding interval, $[a, \frac{a+b}{2}]$ or $[\frac{a+b}{2}, b]$ respectively.

El-Abd and Kamel [3] introduced PSO_Bounds, in which the concepts of PBIL are integrated into PSO. At the beginning of the algorithm, the particles are initialized in the predefined domain. After every iteration, the probability h_d of each dimension d is adjusted according to the probability of the value associated with this dimension being in the *high* interval of the defined domain. To prevent premature convergence, this probability is calculated using information from all the particles and not only g^{best} . Hence, the original equations of PBIL are changed as follows:

$$p_{id}^t = \begin{cases} 0 & \text{if } p^{best}_{id} < \frac{a+b}{2} \\ 1 & \text{otherwise} \end{cases}$$
$$p_d^t = \frac{\sum_i^n p_{id}^t}{n}$$
$$h_d^{t+1} = (1 - \alpha) * h_d^t + \alpha * p_d^t \quad (3)$$

where $i \in \{1..n\}$ and n is the number of particles, t is the iteration number, and d is the dimension.

In PBIL, the probabilities were updated using the value of the best individual, which is analogous to the current position of the particles in PSO. However, in our implementation, we use the values of p^{best} instead because these values reflect the best experience of the swarm and would guide the search towards better solutions. When h_d becomes specific enough, the domain of dimension d is adjusted accordingly, and h_d is re-initialized to 0.5. In this model, different dimensions may end up having different domains and different velocity bounds which do not happen in normal PSO.

In order to overcome the problem of the bounds overlapping, thus preventing further particle movement, the width

of the adjusted bounds is taken into consideration if the algorithm needs to adjust these bounds for a certain dimension d . If the width drops below a predetermined percentage of the initial search domain width, controlled by the parameter T , the bounds are reset to the initial bounds of the search space and the velocity component is also re-initialized. This will allow the particles to move in different directions and in large steps in the next iteration while still taking the old $pbest$ and $gbest$ information into account, hence, not losing any previous information gathered during the search.

Fig. 1 shows the MATLAB code for PSO_Bounds where x_{dmin} and x_{dmax} refer to the minimum and maximum bounds for dimension d while v_{dmin} and v_{dmax} refer to the velocity bounds.

3. RESULTS

The parameters are set as $c1 = c2 = 2$, w linearly decreases from 0.9 to 0.1 with the iterations 40 particles are used, $h_{dmin} = 0.2$, $h_{dmax} = 0.8$, $\alpha = 0.05$ and $T = 0.0001$.

The simulations for 2; 3; 5; 10 and 20 D were done with the MATLAB-code and took 12 hours and 15 minutes. No parameter tuning was done and the crafting effort CrE [6] is computed to zero.

Results from experiments according to [5] on the benchmark functions given in [4, 6] are presented in Figures 2 and 3 and in Table 1.

4. CPU TIMING EXPERIMENT

For the timing experiment PSO_Bounds was run with a maximum of 10^4 function evaluations and restarted until 30 seconds has passed (according to Figure 2 in [6]). The experiments have been conducted with an Intel Core 2 Quad 2.4 GHz under Windows XP using the MATLAB-code provided. The time per function evaluation was 1.2; 1.6; 1.6; 1.8; 2.1 times 10^{-5} seconds in dimensions 2; 3; 5; 10; 20 respectively.

Figure 1: PSO_Bounds MATLAB-code.

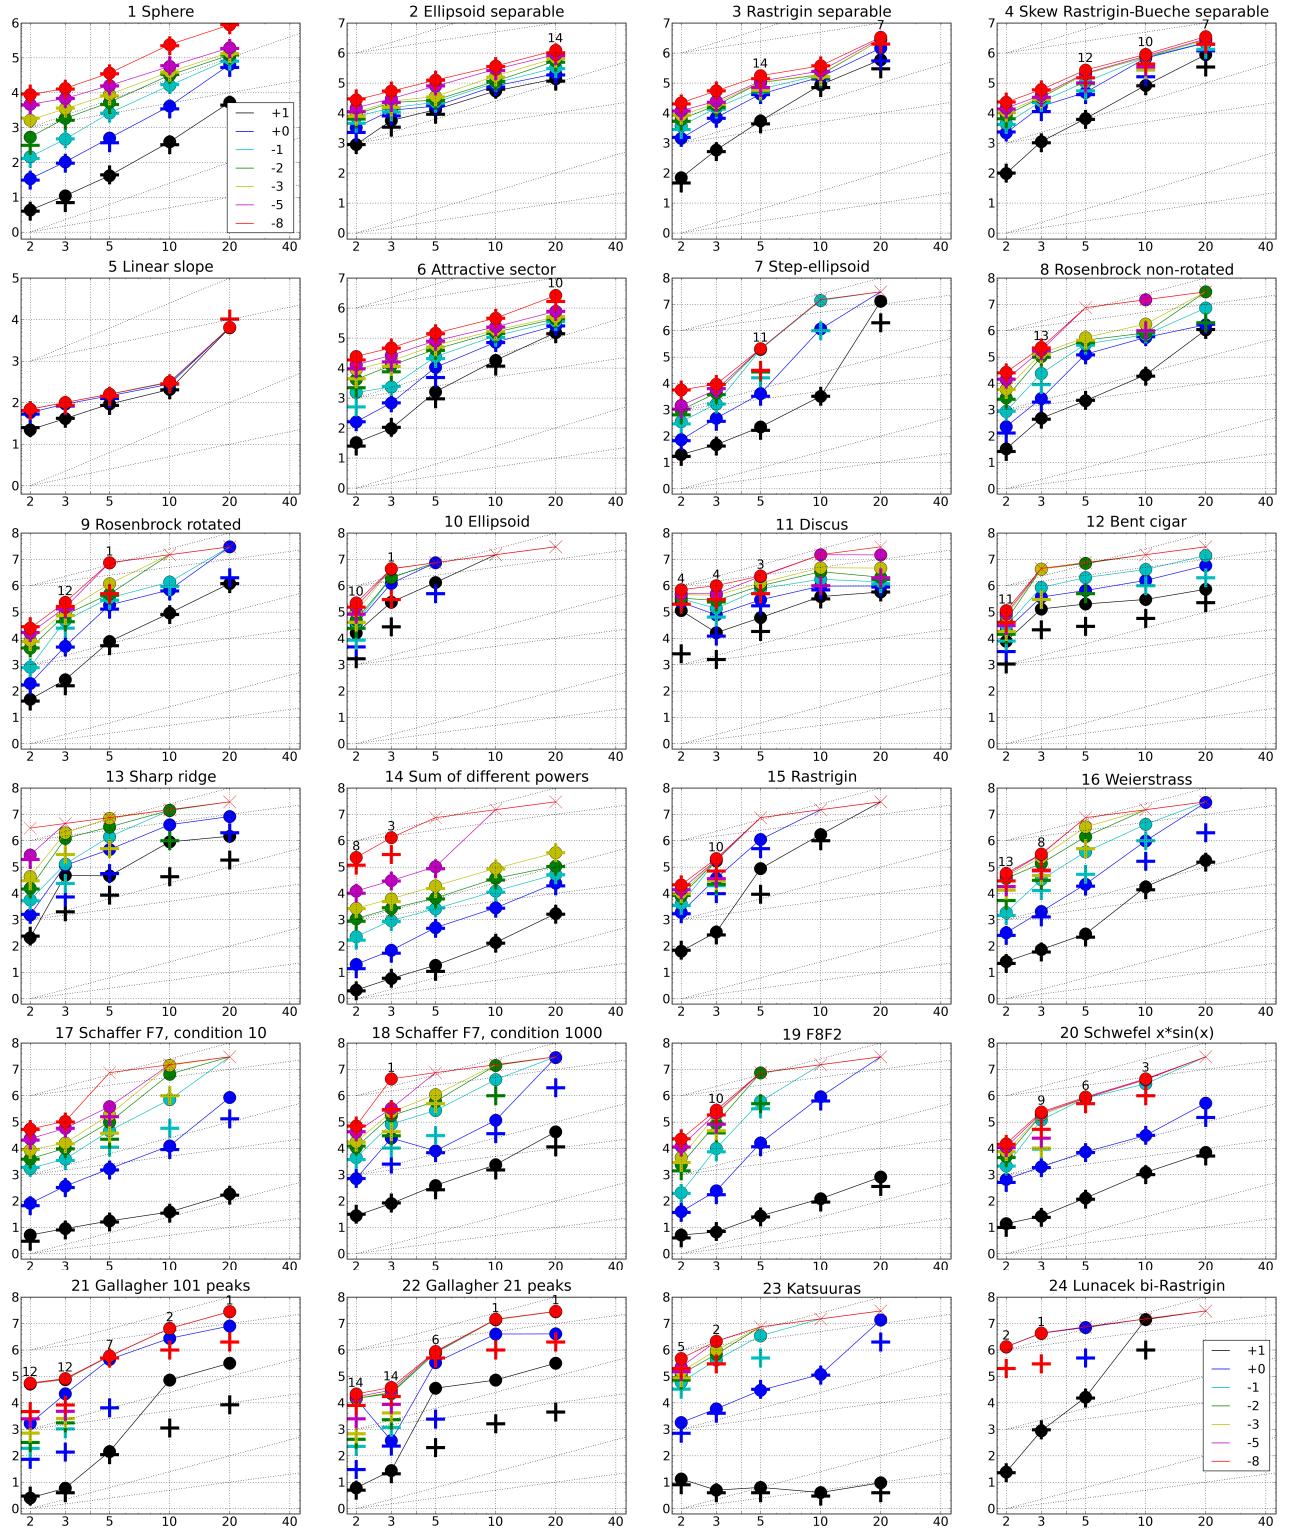

Figure 2: Expected Running Time (ERT, ●) to reach $f_{\text{opt}} + \Delta f$ and median number of function evaluations of successful trials (+), shown for $\Delta f = 10, 1, 10^{-1}, 10^{-2}, 10^{-3}, 10^{-5}, 10^{-8}$ (the exponent is given in the legend of f_1 and f_{24}) versus dimension in log-log presentation. The $\text{ERT}(\Delta f)$ equals to $\#\text{FEs}(\Delta f)$ divided by the number of successful trials, where a trial is successful if $f_{\text{opt}} + \Delta f$ was surpassed during the trial. The $\#\text{FEs}(\Delta f)$ are the total number of function evaluations while $f_{\text{opt}} + \Delta f$ was not surpassed during the trial from all respective trials (successful and unsuccessful), and f_{opt} denotes the optimal function value. Crosses (×) indicate the total number of function evaluations $\#\text{FEs}(-\infty)$. Numbers above ERT-symbols indicate the number of successful trials. Annotated numbers on the ordinate are decimal logarithms. Additional grid lines show linear and quadratic scaling.

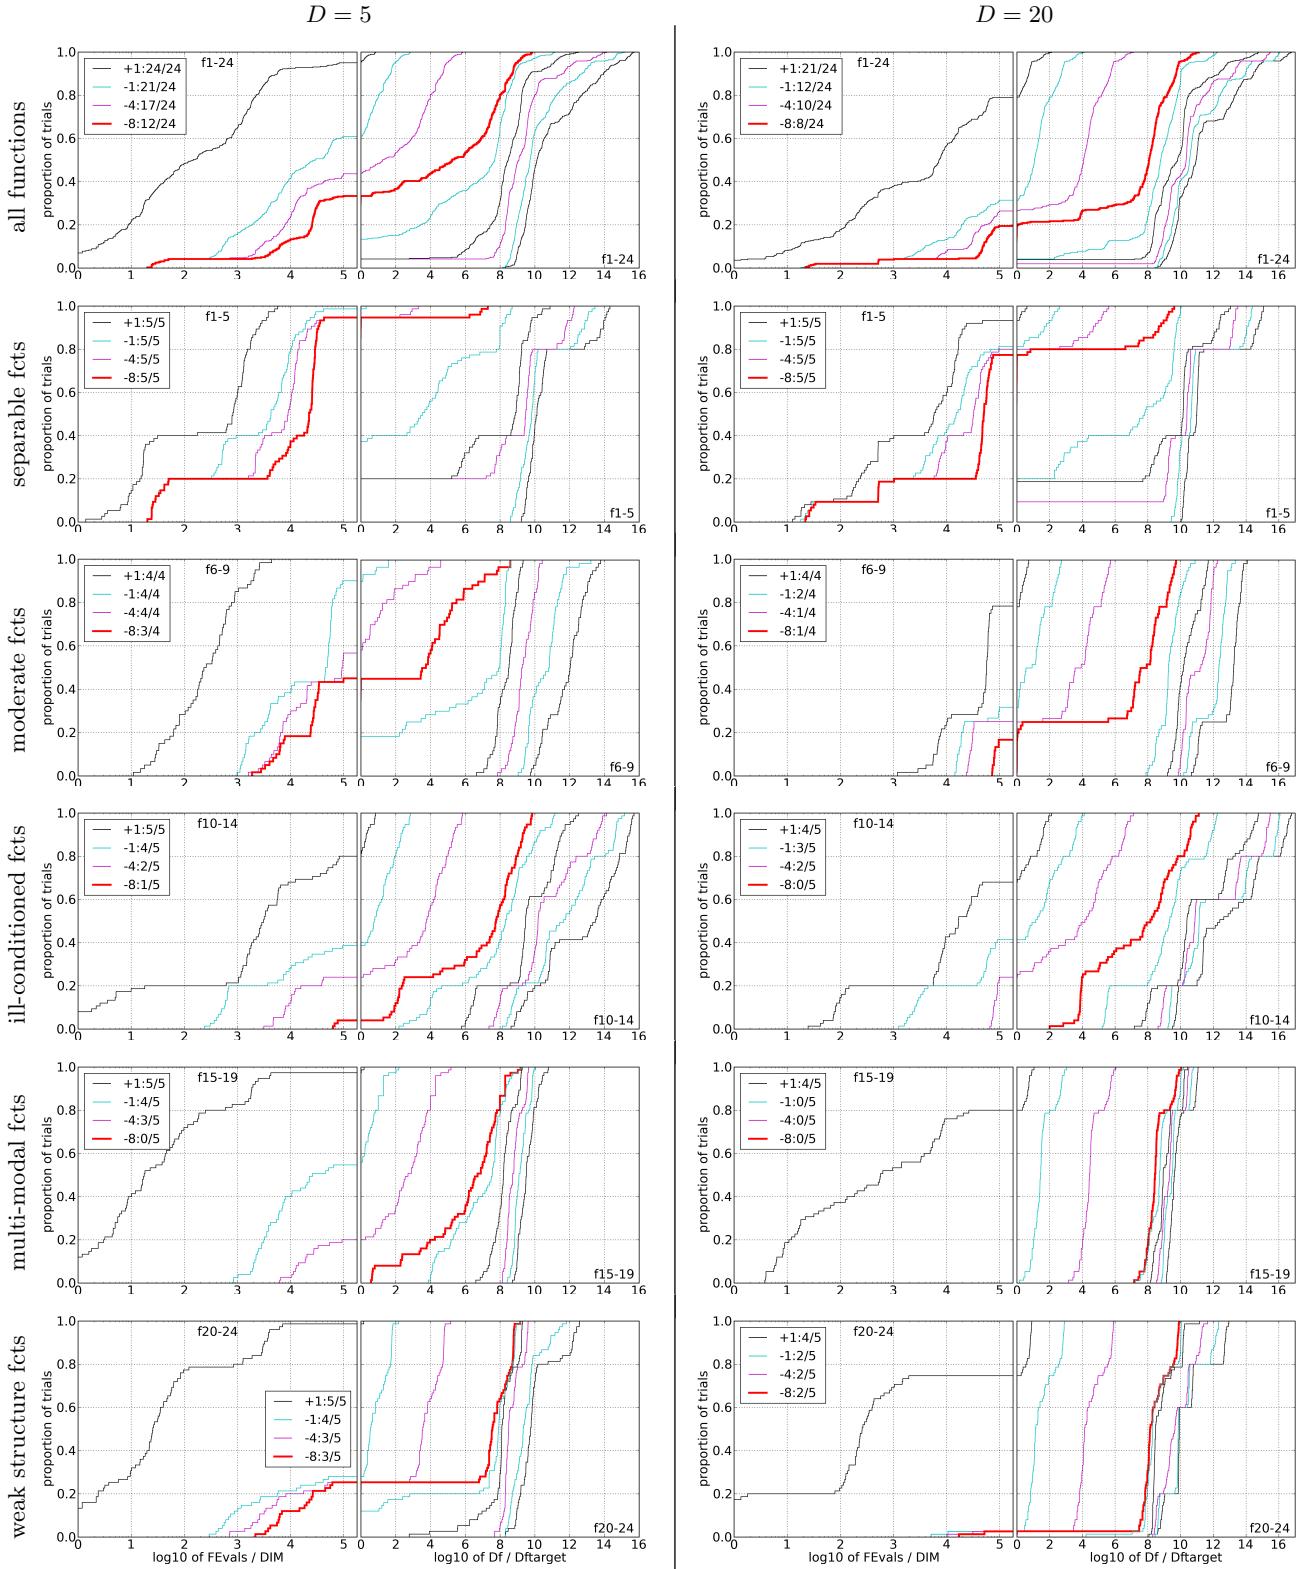

Figure 3: Empirical cumulative distribution functions (ECDFs), plotting the fraction of trials versus running time (left) or Δf . Left subplots: ECDF of the running time (number of function evaluations), divided by search space dimension D , to fall below $f_{\text{opt}} + \Delta f$ with $\Delta f = 10^k$, where k is the first value in the legend. Right subplots: ECDF of the best achieved Δf divided by 10^k (upper left lines in continuation of the left subplot), and best achieved Δf divided by 10^{-8} for running times of $D, 10D, 100D \dots$ function evaluations (from right to left cycling black-cyan-magenta). Top row: all results from all functions; second row: separable functions; third row: misc. moderate functions; fourth row: ill-conditioned functions; fifth row: multi-modal functions with adequate structure; last row: multi-modal functions with weak structure. The legends indicate the number of functions that were solved in at least one trial. FEvals denotes number of function evaluations, D and DIM denote search space dimension, and Δf and Df denote the difference to the optimal function value.
